into a narrow mouth, a feature which is found in all Aran basket-work. Miss Gahan of the Irish Homespun Society regards it as an adaptation to the conditions on the islands, for the contents might easily be spilled owing to the number of loose stone walls which have to be crossed on a journey to the fields. Many of the Aran carrying baskets (" kishauns ") are constructed of coiled straw rope bound together with split bramble (Fig. 77). They no doubt help to keep warm the food carried in them, such as boiled potatoes, boiled in their skins needless to say, in the Irish fashion. Such " lipe-work " was once common in Wales, where seed-baskets, yarn-holders, hassocks and meal containers were made in this way, but in Ireland the only coiled work I have seen outside the Aran Islands is the bee-skep of rye straw, tied with bramble. The illustration shows the small bone pin or awl used by the islanders in threading the brambles. Similar pins, which doubtless had many uses, are frequently found in archæological excavations, particularly on sites where a Mesolithic heritage may be suspected.

Note bone pin.

This brings us to the very large topic of the uses made of straw. There is no need to refer to the value of oat straw as fodder or as thatch, though it does not last long as roofing material, and either wheat or rye straw is preferred. A humble example of the use of thatch is shown in the beehive (Fig. 77*a*) Rope (sugán) made of straw or hay still finds many uses, especially for tying down thatch on houses and stacks. It is twisted on a " thraw-hook " of ash or hazel, with a sally hand-grip, but the old styles are declining with the spread of a simple " twister " of strong bent wire (Fig. 78). This type is found throughout the British Isles in many forms some of which are
